

C#: GET/SET

GET- SET

- accessors used within properties to control how a class's fields are accessed and modified.
- provide a mechanism for encapsulation, allowing hiding implementation details and add logic during data retrieval or assignment.

GET()

- retrieve the value of a property.
- When you read the value of a property, the get accessor is invoked.
- We can include custom logic within the get block, such as calculations or data formatting, before returning the value.

SET()

- used to assign a value to a property.
- When you **assign** a value to a property, the set accessor is invoked.
- Within the set block, the value keyword represents the incoming value being assigned.
